

Spaced Repetition: Warming the Memory Cache

The Only Scientific Strategy Against Forgetting · Printable Plate

Curva: Functio Oblivionis Ebbinghausiana

I. THE CURVE

II. OBSERVATIONS

Obs. 1

Forgetting is Front-Loaded

50% of content is forgotten within 1 hour, but the rate slows dramatically after 1 day. The first review is the most critical.

Obs. 2

Spacing > Massing

The same study time spread over 10 days is 2-3× more effective than crammed into 1 day. Continuous reading creates an "illusion of fluency."

Obs. 3

Retrieval > Rereading

Active recall (self-testing with the book closed) is 50% more effective than passive rereading. Testing is a learning tool, not just assessment.

Obs. 4

Review at the Edge of Forgetting

Reviewing when you're "about to forget but haven't yet" yields the strongest memory consolidation. Too frequent wastes effort; too sparse loses progress.

METHODS

- 1 Review before sleep** — Active recall 8-12 hours after learning boosts retention from 40% to 80%.
- 2 Use spaced repetition software** — Anki, RemNote, etc. have built-in algorithms that schedule optimal review intervals automatically.
- 3 Test yourself first, then check** — Forcing your brain to retrieve in "hard mode," even if wrong, is more effective than immediately seeing the answer.
- 4 Interleave different topics** — Don't study one chapter at a time; mix reviews. The brain builds stronger connections through switching.
